but **only** when baseline LDL-C levels were **100mg/dL or greater** (P < .001 for interaction)

RR per 40-mg/dL baseline LDL-C increase, 0.86 (95% CI, 0.80-0.94); P < .001

Meta-analysis of **Cardiovascular Mortality** Stratified by Baseline LDL-C Level

Meta-regression Analysis of **MACES** by Baseline LDL-C Level

Association Between Baseline LDL-C Level and Total and Cardiovascular Mortality After LDL-C Lowering A Systematic Review and Meta-analysis

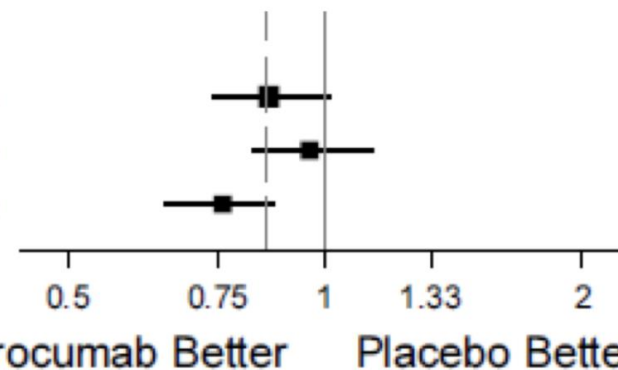

Eliano P. Navarese, MD, PhD; Jennifer G. Robinson, MD, MPH; Mariusz Kowalewski, MD; Michalina Kołodziejczak, MD; Felicita Andreotti, MD; Kevin Bliden, MD; Udaya Tantry, PhD; Jacek Kubica, MD, PhD; Paolo Raggi, MD; Paul A. Gurbel, MD

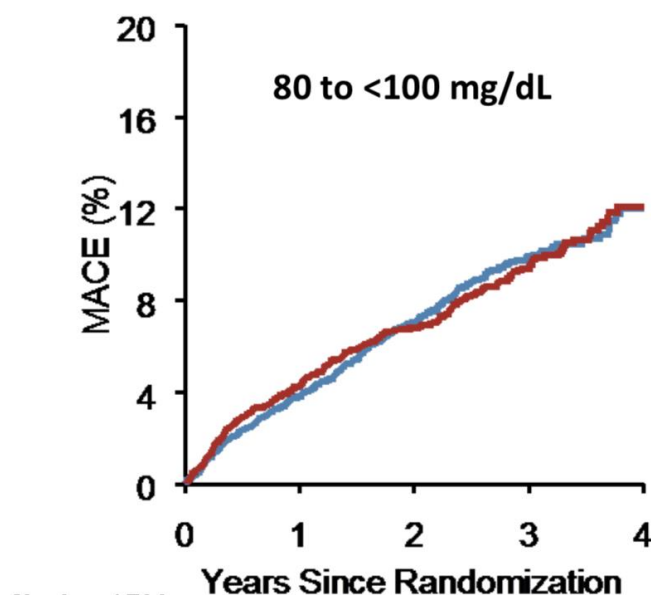

CONCLUSIONS AND RELEVANCE In these meta-analyses and meta-regressions, more intensive compared with less intensive LDL-C lowering was associated with a greater reduction in risk of total and cardiovascular mortality in trials of patients with higher baseline LDL-C levels. This association was not present when baseline LDL-C level was less than 100 mg/dL, suggesting that the greatest benefit from LDL-C-lowering therapy may occur for patients with higher baseline LDL-C levels.

Marzal D.

Máxima reducción de colesterol unido a lipoproteínas de baja densidad alcanzable con combinaciones farmacológicas. Cuando 50 más 20 suma 60

Por ejemplo, cuando se emplean estatinas en monoterapia (con un efecto máximo de reducción de LDL del 50%), solo los pacientes con LDL < 140 mg/dl alcanzarán los objetivos de prevención secundaria (LDL < 70 mg/dl). Con el uso de una estatina más ezetimiba (capacidad máxima de reducción de LDL del 60%), solo los pacientes con LDL < 175 mg/dl alcanzarán los objetivos de prevención secundaria.

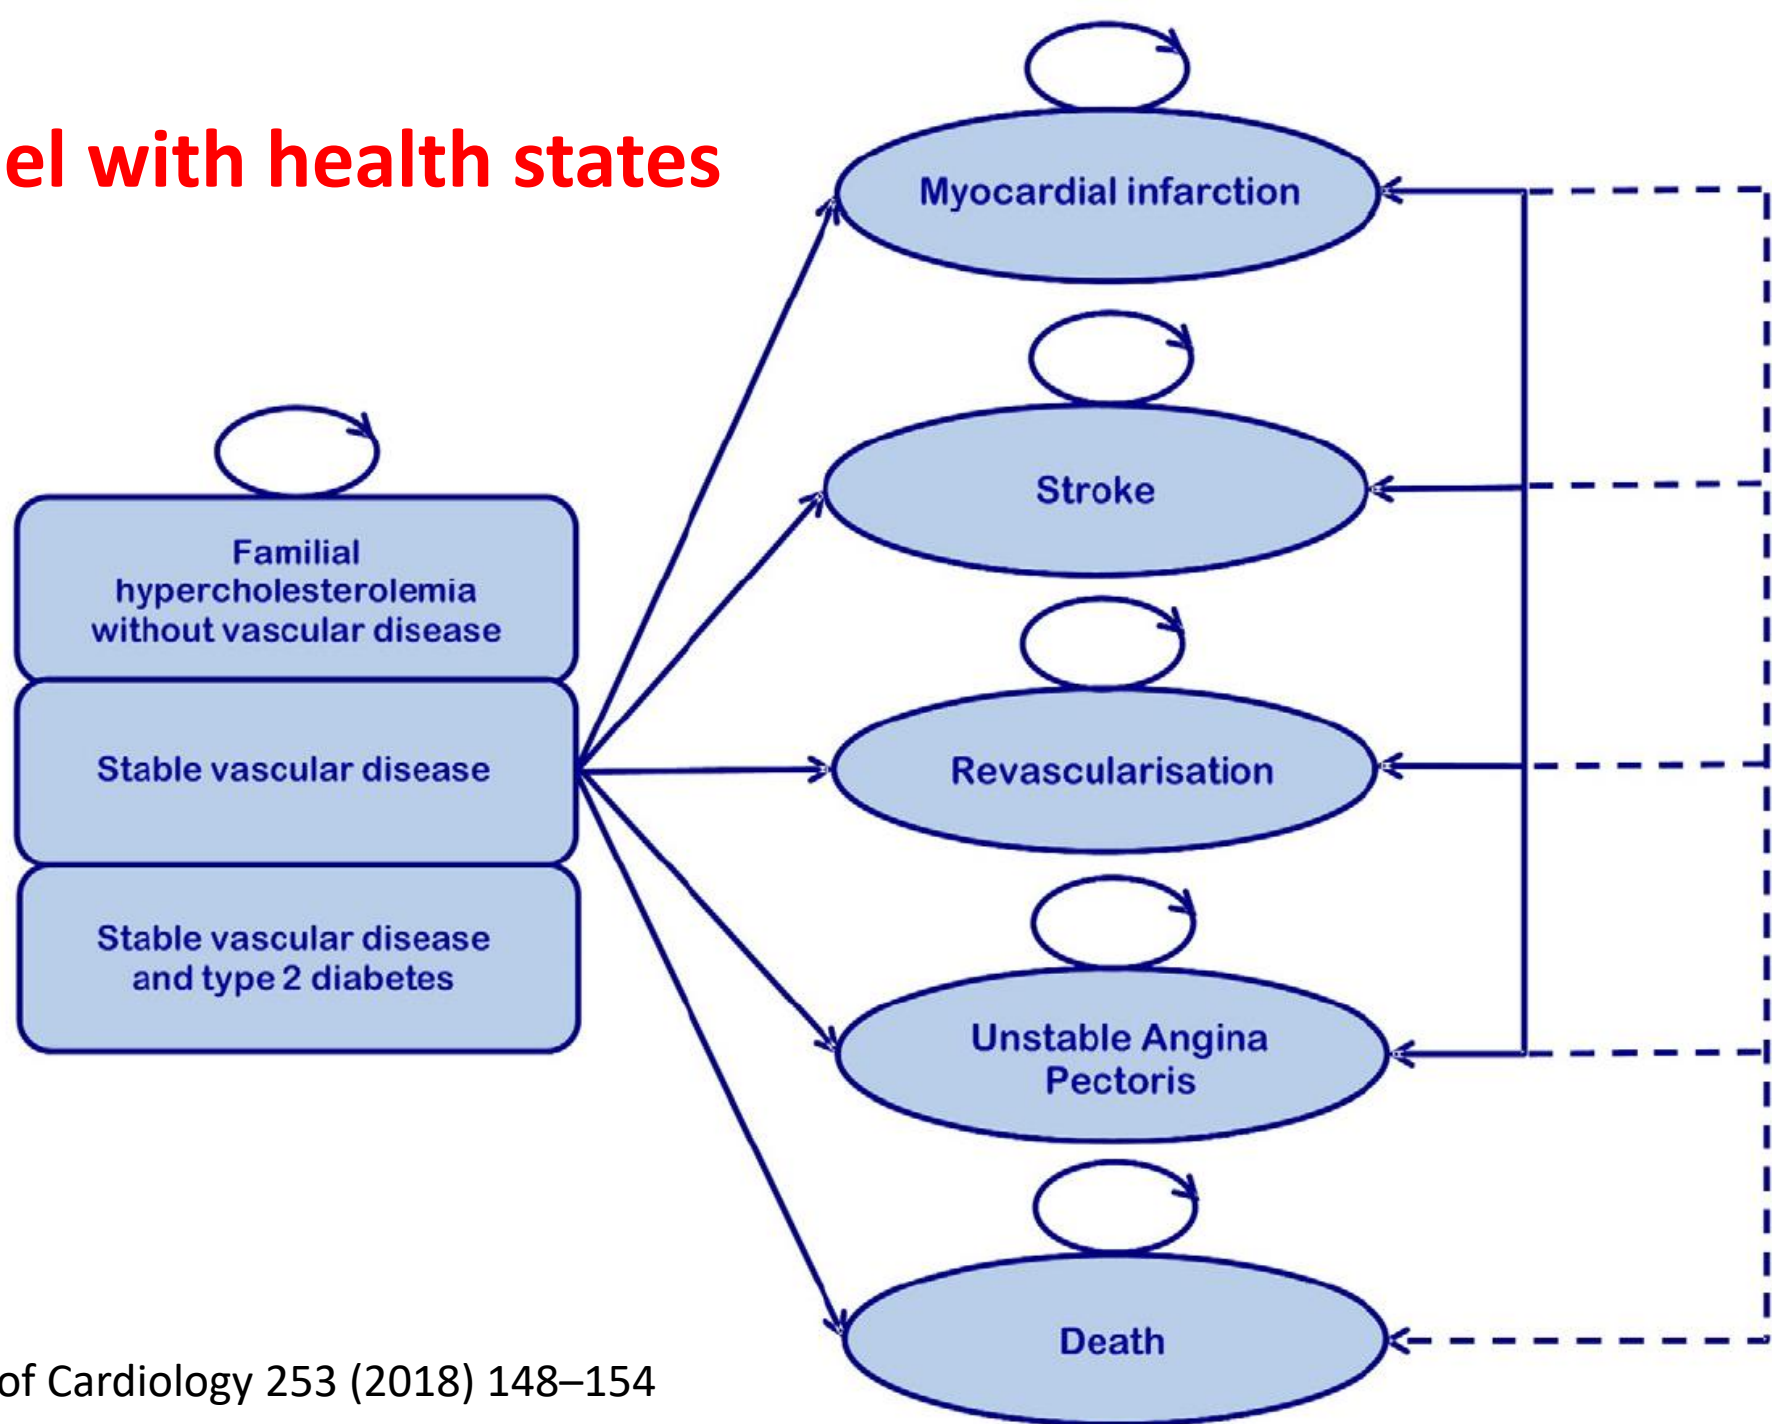

Con la terapia triple (capacidad de reducción de LDL del 84%), prácticamente todos los pacientes con LDL \leq 437 mg/dl podrían alcanzar los objetivos de LDL recomendados para la prevención secundaria.

RESUMEN

Introducción y objetivos: Analizar la razón de coste-efectividad y el tratamiento con evolucumab (inhibidor de la PCSK9) para pacientes en Sistema Nacional de Salud español.
Método: Se realizaron, desde la perspectiva del sistema sanitario y presupuestario, modelos de árbol de decisión y Markov, basándose en el 6 de morbimortalidad (FOURIER). Las alternativas comparadas fueron evolú 5S ezetimípara conjuntamente. La medida de efectividad utilizada fue el número de eventos. Se realizaron análisis de sensibilidad univariable y probabilístico. **Resultados:** El coste sanitario promedio de los pacientes tratados a 20 € 11.134,78 euros y de 303,83 euros con el estándar (estatinas + ezetimípara) incrementó los 600.000 euros por evento cardiovascular evitado muerte cardiovascular, infarto de miocardio, accidente cerebrovascular isquémico o revascularización coronaria; segunda: incluye los 3 primeros de de Markov mostró un coste promedio de 471.417,37 frente a 13.948,49 eur respectivamente. El tratamiento con evolucumab en hipercolesterolemia (entre 3 y 6,1 millones de euros, lo que supone una diferencia de 2,5 de tratamiento estándar (2017). Para el año 2021, en hipercolesterolemia secundaria), la diferencia osciló entre 204,3 y 1.364,7 millones de euros. **Conclusiones:** El evolucumab se asocia con menor frecuencia de eventos e ineficiente para los pacientes susceptibles de recibirlo en el Sistema Nacional de Salud Española de Cardiología. Publicado por Elsevier España, S.L.U.

Cost-effectiveness and budget impact of Treatment With Statins and Ezetimibe for Hypercholesterolemia in Spain

ABSTRACT

Introduction and objectives: To analyze the cost-effectiveness ratio and budget impact (PCSK9 inhibitor) for patients in secondary prevention in Spain.
Method: A budget impact analysis, decision tree and Markov models were health systems perspective, based on the only study with morbidity and mortality alternatives compared were evolucumab vs statins, and dual therapy population. The measure of effectiveness used was the number of cardiovascular events. Sensitivity analyses were performed.
Results: The average annual cost of patients receiving evolucumab was standard treatment (statins plus ezetimibe). The incremental cost-effectiveness ratio was not advantageous event for both assessed outcomes (first: card

1. Introduction
3-Hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors (statins) are highly efficacious at reducing low density lipoprotein cholesterol (LDL-C) levels and lowering CVD risk [1] and currently comprise first-line therapy in the treatment of hyperlipidaemia and prevention of CVD [2]. Previous research has demonstrated that a decrease of 1 mmol/L LDL-C results in an approximate 20% decrease in risk of CVD major vascular events [3].

However, statins are available for approximately 5 to 10% of individuals, predominantly due to intolerance or inefficacy as monotherapy [4]. For such people, the new class of lipid lowering agents, proprotein convertase subtilisin/kexin type 9 inhibitors (PCSK9), represents an alternative treatment option. Randomized controlled trials of PCSK9 thus far have demonstrated reductions in LDL-C levels by

Abstract
Purpose of Review This review aims to explore and summarize the current literature on the cardiovascular health care burden and the cost-effectiveness of the PCSK9 inhibitors.

Recent findings The CVD remains the largest cause of mortality in the USA, presenting substantial health care burden, but in price of ~1,400–14,600 per patient per year coupled with ~2.2–2.8 years of cardiovascular risk, but their cost-effectiveness has been questioned. We searched Medline and Embase for economic evaluations in any language at any time. Studies were included if they analyzed any PCSK9 inhibitor compared with either statin alone or in combination with ezetimibe or any other therapy considered standard prior to the introduction of PCSK9 inhibitors. We found ten full health economic evaluations of PCSK9 inhibitors, two from Europe and eight from the United States (US). Six of the eight from the US were from two different countries that analyzed PCSK9 inhibitors at different stages through the development of evidence. All studies generally reported incremental cost-effectiveness ratios above suggested thresholds for cost-effectiveness, except one study from the United Kingdom and France [1].

Keywords Almonaximab · Evolocumab · PCSK9 · Cardiovascular · Cholesterol · Lipoprotein (a)

Introduction

The cardiovascular diseases (CVD) remain the leading cause of death globally with the mortality rates between 481 and 680 deaths per 100,000 people in western Europe, northern Asia, Middle East, and some parts of Africa [1, 2]. There were 42.7 million cases of CVD worldwide with 17.92 million deaths as per the 2015 estimate [1, 2]. The CVD remains the number one cause of mortality in the USA, accounting for about one in three deaths [3]. The striking CVD statistics from 2013 shows that ~2200 Americans die due to the CVD every day, one death every 40 s [3, 4]. The stroke caused 1 in 20 deaths while the coronary heart disease (CHD) caused 1 in 7 deaths in 2013 [3, 4]. Each year, approximately 795,000 Americans continue to experience a new recurrent stroke and ~

665,000 Americans have a new or recurrent stroke and ~160 in strokes each year [2].

Hendriksen et al. estimated that approximately 20% of the US population will have some form of CVD by 2030. However, as per the American Heart Association (AHA) projections on prevalence of CVD in 2015, (102.7 million) Americans had at least one of the following conditions: hypertension, coronary heart disease, heart failure, or atrial fibrillation [2015]. The CVD burden is expected to increase further [5].

The estimation of the cardiovascular burden is complex due to the imperfect science with the ACC/AHA guideline having its limitations such as its focus on CVD events, and limiting the trip and systemic blood pressure [6, 7]. For a risk of the atherosclerotic cardiovascular disease as opposed to the short-term 10-year risk, the incorporation of soft ASCVD outcomes, such as heart failure, transient ischemic attack, intermittent claudication, as well as a larger younger individuals suffer from soft A

Leeming et al. concluded that two thirds of the CVD burden is preventable.

ABSTRACT

Randomized trials have shown marked reductions in low-density lipoprotein cholesterol (LDL-C), a risk factor for cardiovascular disease (CVD), when evolocumab is administered. We hypothesized that evolocumab added to standard of care (SOC) vs SOC alone is cost-effective in the treatment of patients with heterozygous familial hypercholesterolemia (HeFH) or atherosclerotic CVD (ASCVD) with or without statin intolerance and LDL-C >100 mg/dL. Using a Markov cohort state transition model, primary and recurrent CVD event rates were predicted considering population-specific trial-based mean risk factors and calibrated against observed rates in the real world. The LDL-C-lowering effect from population-specific phase 3 randomized studies for evolocumab was used together with estimated LDL-C-lowering effect on CVD event rates per 38.67-mg/dL LDL-C lowering from a statin-trial meta-analysis. Costs and utilities were included from published sources. Evolocumab treatment was associated with both increased cost and improved quality-adjusted life-years (QALY): HeFH (incremental cost: US\$153 289, incremental QALY: 2.02, incremental cost-effectiveness ratio: US\$75 863/QALY); ASCVD (US\$158 307, 1.12, US\$141 699/QALY); and ASCVD with statin intolerance (US\$136 903, 1.36, US\$100 309/QALY). Evolocumab met both the American College of Cardiology/American Heart Association (ACC/AHA) and World Health Organization (WHO) thresholds in each population evaluated. Sensitivity and scenario analyses confirmed that model results were robust to changes in model parameters. Among patients with HeFH and ASCVD with or without statin intolerance, evolocumab added to SOC may provide a cost-effective treatment option for lowering LDL-C using ACC/AHA intermediate/high value and WHO cost-effectiveness thresholds. More definitive information on the clinical and economic value of evolocumab will be available from the forthcoming CVD outcomes study.

Introduction

Approximately 86 million people in the United States have cardiovascular disease (CVD); it accounts for 1 out of every 3 deaths and remains the leading cause of death.¹ Despite the widespread use of statins, the economic burden associated

with CVD is onerous, with > US\$650 billion spent on CVD-related costs annually in the United States.² These costs are projected to nearly double by 2030.³ The cost-effectiveness of new therapies has become increasingly important as healthcare costs continue to rise and information about making tradeoffs becomes critical.

Low-density lipoprotein cholesterol (LDL-C) has been established as a modifiable risk factor for CVD. A meta-analysis conducted by the Cholesterol Treatment Trialists' Collaboration (CTTC) found that every 38.67-mg/dL (1 mmol/L) reduction in LDL-C with statin therapy results in a 21% (statins vs control) and 26% (more vs less statins) reduction in rates of any major CVD event across 26 randomized trials.³ Results from the Improved Reduction of

ABSTRACT

Randomized trials have shown marked reductions in low-density lipoprotein cholesterol (LDL-C), a risk factor for cardiovascular disease (CVD), when evolocumab is administered. We hypothesized that evolocumab added to standard of care (SOC) vs SOC alone is cost-effective in the treatment of patients with heterozygous familial hypercholesterolemia (HeFH) or atherosclerotic CVD (ASCVD) with or without statin intolerance and LDL-C >100 mg/dL. Using a Markov cohort state transition model, primary and recurrent CVD event rates were predicted considering population-specific trial-based mean risk factors and calibrated against observed rates in the real world. The LDL-C-lowering effect from population-specific phase 3 randomized studies for evolocumab was used together with estimated LDL-C-lowering effect on CVD event rates per 38.67-mg/dL LDL-C lowering from a statin-trial meta-analysis. Costs and utilities were included from published sources. Evolocumab treatment was associated with both increased cost and improved quality-adjusted life-years (QALY): HeFH (incremental cost: US\$153 289, incremental QALY: 2.02, incremental cost-effectiveness ratio: US\$75 863/QALY); ASCVD (US\$158 307, 1.12, US\$141 699/QALY); and ASCVD with statin intolerance (US\$136 903, 1.36, US\$100 309/QALY). Evolocumab met both the American College of Cardiology/American Heart Association (ACC/AHA) and World Health Organization (WHO) thresholds in each population evaluated. Sensitivity and scenario analyses confirmed that model results were robust to changes in model parameters.

Among patients with HeFH and ASCVD with or without statin intolerance, evolocumab added to SOC may provide a cost-effective treatment option for lowering LDL-C using ACC/AHA intermediate/high value and WHO cost-effectiveness thresholds. More definitive information on the clinical and economic value of evolocumab will be available from the forthcoming CVD outcomes study.
